1

Everyday traders can compose alpha using publicly available token data.

This is an observation that meaningful token analyses exist abundantly but are fragmented across platforms, dashboards, tools, and private communities. Each contains some useful information, but there is significant noise to sift through to get to it. This project demonstrates how developers can build modular token analyses that integrate into a browser extension for traders to tailor and augment their research capacity. These we call **data modules**. Each data module analyzes one meaningful aspect of a token's design or distribution such as wallet clusterings, top holder activity, liquidity changes, contract risks, off-chain sentiment, volume spikes, dev history, or any other kind of "alpha" signal that someone wants to capture data on.

Should the use of this kind of token analytics tool see growth, agentic AI could be employed to learn which data modules are relied on the most by traders across the ecosystem; or said another way, which token analyses actually pattern match with volume spikes and at what reading. The result represents a novel composition of trading alpha through the capture of high signal public token data. This is a discovery project for developers, analysts, and those who believe that doing your own research could be way cooler.

2

The Dragon Project

A working prototype extension is live now on the [Chrome Web Store](#). To use it, paste a pump.fun token CA to the bar at the top. Real-time data will be pulled on that token using a handful of off-chain sources. This demonstrates how token analyses that source from various locations can be composited in your sidebar as you make your trades or conduct research. In the future, this becomes a trading companion that learns patterns in market data and brings intelligence to traders.

A future version of the extension would use a wallet to sign in and authenticate the trader. If a token is bought from that wallet, Dragon could be set to snapshot the trader's chosen analyses at the time of purchase. This builds the **trader's profile**, learning preferred metrics of tokens they tend to purchase. This allows discovery of new tokens that may be of interest based on the profile. Read-only to the wallet keeps security risks low and trader utility high.

For a demonstration of the Dragon prototype, you can see an old [walk through video here](#). You can also download the codebase for yourself at the [Github here](#). Please note that downloading and using Dragon is for informational purposes only and not to be interpreted as financial advice.

Modularity

A key feature of the extension is its modular architecture. Each token analysis is contained within a single **data module, developed and integrated by the Dragon community**. Modules evaluate any single design aspect of a token such as its liquidity, smart money holdings, creator activity, or sniper history. There are currently four working data modules on the prototype that fetch data from reputable analysis platforms on the web.

Token Info
(pump.fun + Trenchy Bot)

Sniper Analysis
(Trenchy Bot)

**Clustered Wallets +
Top 10 Holders**
(Bubblemaps + Solscan)

Jito Bundled Wallets
(trench.bot)

The Open Playground

To facilitate open exploration for Dragon’s technical users, an empty Dragon shell can be downloaded [from GitHub](#) and run locally on Chrome as an extension. A live webpage called the **Playground** allows developers to download data modules as individual packages that plug into their local Dragon. Modules are published by other developers around the world and can be voted on for significance in contribution to volume signaling (more details about this and how AI can facilitate in the next section). Each module shared on the Playground can present a name, a thumbnail, data inputs used, APIs required, and a description of the token analysis that it produces for the user.

Treat the Playground as a discovery and distribution layer, not a remote-code execution layer. Please keep in mind that community modules are not guaranteed to be audited, accurate, safe, or maintained. Users should always inspect the module code and install modules at their own risk.

Project Assets

Prototype. The prototype comes ready with four data modules for traders to use. The intent is to experience having token analyses as a browser companion. Download it from the [Chrome Web Store](#)

Local Extension. A fully-customizable Dragon extension shell can be downloaded from [Github](#) and hosted locally. Developers can create data modules of their own or download community developed modules that plug in to their local extension.

Data Modules. These are the plug-in token analyses that can be customized on anyones local Dragon. These can be developed and shared by other Dragon users on the open [Playground](#).

Prototype

Extension

Data Modules

Contributor Recap

1. Download a Dragon local extension from [Github](#)
2. Download any module available on the open [Playground](#)
3. Build your own data modules and plug into your local Dragon
4. Share your modules with other people on the Playground
5. Have fun, and review all the docs!

3

Patterns + Magic = Alpha

In this section we put forward some agentic approaches to composing alpha from patterns found in the abundant data scattered online. The purpose for our exploration is to sketch a larger vision for data module development. While developing modular token analyses can be a fun exploration in itself, connecting and coordinating the signals in the best of them can provide substantial value to traders, researchers, and potentially the ecosystem in general.

Pattern Engine

A **Pattern Engine** can orchestrate multiple analysis inputs upon detecting a meaningful token event, such as a volume anomaly, pump, rug, or sharp liquidity change. As a modular ensemble observatory, it can fuse selected on-chain signals like DEX volume, wallet flows, holder concentration, sniper exposure, bundle activity, liquidity movement, and MEV activity with selected off-chain indicators such as social sentiment, news, alpha-group chatter, or narrative data. As discussed earlier, these analysis inputs come from open-source data modules. The most useful modules can become candidates for deeper study, evaluation, and eventual integration into the Pattern Engine.

The system does not have to rely on noisy real-time data streams in order to begin learning. Instead, it can identify historically significant market windows and capture a snapshot of module outputs during those moments. These time-bounded, high-impact event windows can become the training corpus for understanding which combinations of token signals tend to appear around meaningful market behavior.

For example, if past event data in pump.fun tokens shows that sharp increases in Sniper % combined with flat Bundle % and rising liquidity often appear in a certain kind of frontrun-pump scenario, the Pattern Engine can learn that as a historical pattern. When similar conditions appear in a new token, the system can surface the resemblance as context, not as a hard claim or prediction, but as a scenario supported by historical precedent.

Pattern Engine can eventually render two kinds of output:

1. A quantitative score that reflects how strongly current token conditions resemble known historical scenarios.
2. A qualitative explanation that helps a human trader understand which module signals contributed to the pattern match.

This gives Dragon a path from displaying individual analyses towards helping traders understand how those analyses may interact.

Module Trust and Evaluation

A core challenge in token markets is confounding. Many variables change at the same time: liquidity, volume, social attention, holder distribution, sniper activity, and broader market conditions. Pattern Engine should not pretend to isolate one perfect cause. Instead, it can rely on a spread of modular inputs weighted by context.

Each module can be evaluated by how well its outputs align with significant historical market changes. Stronger modules earn more trust inside the system. We can imagine this as a shared trust layer that updates the weight of each module based on its historical signal quality.

This could be extended with an AI evaluation layer that replays historical token events, compares agent claims against known outcomes, tests module regressions, tracks confidence drift, and flags unstable conclusions before a module influences trader-facing scores. In practice, this gives Dragon a way to test new modules and AI behaviors before promoting them into a more trusted path.

Magic Filter

If Pattern Engine is the ecosystem-level pattern analyzer, **Magic** is the personalized counterpart designed to augment a trader's own data profile.

Every time a user makes an on-chain transaction, a future Dragon with Magic enabled could snapshot the active data modules used by the trader. Over time, those snapshots can help form a trader profile that encodes the token signals they actually act on, not just the signals they happened to view.

The Magic Filter could eventually weight identity elements such as realized PnL, buy frequency, buy size, holding time, recency, slippage tolerance, risk flags accepted, modules viewed before action, token age at entry, liquidity range, holder

concentration, bundle exposure, sniper exposure, and category preference. This helps separate "signals this trader often acts on" from "signals that were merely visible." Over time, the trader profile becomes more context-aware and can surface future tokens that match both the trader's behavior and the Pattern Engine's ecosystem-level signal quality.

Pattern Engine + Magic Filter = Alpha

Alpha is conceived as a combination of two complementary towers:

1. The trust-weighted analysis patterns passed through the Pattern Engine
2. The trader profile distilled by the Magic Filter

Defining Alpha this way gives traders and developers a stronger path to meet the speed of whales, bots, and insiders in permissionless markets. The execution can be imagined as a browser-level action that rank-matches visible tokens by personal fit and ecosystem pattern strength. A one-click filter could reduce noisy marketplaces like pump.fun to tokens that match the trader's profile and the system's highest-trust pattern signals.

Developing the AI

Everything in this section describes a potential for incorporating AI into Dragon, not the current production status of the project. Future work can test additional agent frameworks (like OpenClaw integration), evaluation harnesses, and module-specific agents as optional integrations around Dragon's open module architecture. The immediate goal for this release is to share the prototype, invite module development, and let the community discover which token analyses are useful enough to continue building on.

4

\$Alpha Token

\$Alpha is being relaunched on Clanker as a community signal token. The creators make no exclusive claim over future development. The sole intent for relaunch is to gauge interest in the project and open contribution of data modules as described. A future state of this token can provide for contributor grants and mechanisms for project decisions if holders wish to organize. The creators remain open to any other recommendations by the community for how this moves forward.

The original \$ALPHA was first launched on Solana with Believe back in June 2025, where it was quickly frozen by the protocol killing over \$1M of volume within 60 minutes of the token generation. The team prefers now to hand the project over to other developers, releasing all ideas and codebase to the public.

Token Design

1. **1% static swap fees** for the project dev team. Clanker adds their own 0.2%.

- Recipient: A Safe with adjustable signatures and voting rules. The two project creators will start as the stewards and exclusive fee recipients.

2. **Vaulted 24% of token supply**. This can be used for potential future marketing, development, infrastructure, and module contributions.

1. First unlock: 7 days from token launch

2. Timeline: linear vest for 4 months following unlock

3. Recipient: Another Saf with adjustable signatures and rules. The two project creators will launch as stewards, will not receive tokens from, and will allow new stewards to join as described below.
4. Intention: Development, infrastructure, marketing, module contribution, grants, liquidity support, other community-approved project needs.

3. **Creator buy of ~0.67 ETH** at launch.

4. **Airdrop of 1%** to previous community and partners of the project. Please note that some of these partners are non-crypto-native, so some supply will be custodied in fresh wallets until they are onboarded.

Safe Stewardship

Following the project's launch, new Safe stewards will be received and reviewed by the community. As a practical starting threshold, support from wallets that represent at least 5% of the circulating, non-vault \$Alpha supply will be considered a sufficient community signal for new steward consideration. The incumbent Safe admins remain responsible for final approval of any new steward until a more formal governance process can be adopted.

Here is a structure for new steward proposals at launch:

- 1% circulating non-vault \$Alpha supply can nominate a steward.
- 5% circulating non-vault supply must support adding that steward, within a voting window of 72 hours.
- A public conversation between the proposed steward and the incumbents is announced and broadcasted live to the \$Alpha community.
- A final vote is taken from the \$Alpha community, completed within another window of 72 hours.
- No single wallet can represent more than 50% of the supporting votes.
- The minimum unique voter count will start at 20 unique holders.
- The incumbent Safe stewards execute a new addition only after reviewing identity, conflicts, and basic trustworthiness over the above described ~1 week public review period.

The project creators state here that we will steward these Safes until 3+ stewards are selected and confirmed to move forward with developing this project. At that point we'll have successfully handed off this project to the new dev team that can take it into the future. The guidelines above are meant to facilitate forward movement, and are subject to change in requirements depending on the practicality of the situation after launch.

Please look for the verified addresses of Dragon's Safes and the Snapshot Space where community voting will take place to be posted on our public channels after launch.

Possible Token Uses for the Community

While the \$Alpha token is launched purely as a community signal, the following are possible directions for how it can be used in the future. Understand that none of these use cases are active at launch.

1. Grants to developers and collaborators for their work, ie. contributing high performing data modules or high impact digital marketing content.
2. Enables a user's access to using premium AI features like Magic and Alpha.
3. Enables a developer's access to the AI features in order to train and develop their own agentic systems.
4. Facilitates a governance mechanism for project management and direction.

5

About the Project Creators

Dragon was created by Harshit and Andrew, who met in a graduate Data Science program in the USA. Harshit is an AI/Software Engineer who worked on generative AI systems at IBM and is now working at Amazon. Andrew works on various startup businesses, currently focused on wellness and spirituality. He previously co-founded Cent/Valuables which drew attention for tokenizing tweets as NFTs, including Jack Dorsey's first tweet ever created.

Both are simple retail traders that learned how much of this game is dominated by whales, bots, and insiders. Dragon is the tool we wanted but didn't have in the trenches. We think others might find it useful and can take this further than we can.

Starting a conversation

Connect in the [Telegram](#) group. Follow the [X](#). Post in the [Github forum](#). Discuss what's next and how to build it.

Developing a data module

Download the shell extension from GitHub and host it locally. Build your own data module and post it to the Playground for others to try out.

For those that want idea starters for new data modules, these were some of the project creators' favorites at the time of original release.

Analysis			Source	What it does	Analysis			Source	What it does
1	KOL / Smart Money Holders	StalkChain		Tracks whether known smart-money wallets, KOLs, or influential traders are holding the token.	9	Time of Day Notifications	@AdamTehc		Surfaces statistically useful trading or launch windows based on time-of-day activity patterns.
2	Sniper & Insider Buy Counter	GMGN		Counts early buyers and potential insider/sniper wallets, including whether they sold or still hold.	10	Token Narrative Profiling	Dexu / cryptokoryo		Categorizes a token by narrative, sector, meme type, community style, or market positioning.
3	JITO Bundle Visualizer	trench.bot		Shows wallets linked through Jito bundle activity, useful for spotting coordinated launches or bundled buys.	11	Liquidity Pool Sandwich Score	sandwiched.me		Scores how vulnerable a token's liquidity pools are to sandwich attacks or MEV extraction.
4	Top 10 Holder Awareness	Solscan		Displays the largest token holders and how much supply is concentrated in their wallets.	12	Top Holder Previous Transaction Behavior	RugChecker		Reviews the past behavior of top holders to flag suspicious, rug-prone, or repeat-pattern wallets.
5	Clustered Wallets	Bubblemaps		Visualizes connected wallet clusters to identify related holders or suspicious distribution patterns.	13	Dev / Deployer Overview	Trenchy Bot		Summarizes deployer wallet history, funding source, previous launches, and current token behavior.
6	Liquidity / Market Cap Ratio	@kompreni		Compares available liquidity against market cap to judge trade depth and price fragility.	14	Holder Trends by Time Held	HolderScan		Breaks holders into cohorts by holding duration and shows whether each group is accumulating or exiting.
7	CT / Whale Holder % and Movement	@dethective		Tracks large holders, Crypto Twitter wallets, and whale movement over time.	15	Essential Security Heuristics	Birdeye (and others)		Checks basic safety signals such as mint status, freeze authority, LP lock, ownership, and contract risks.
8	TikTok / X Sentiment Matching	@PixOnChain		Matches social media attention and viral narratives against token chart or holder activity.	16	Holder Profiles / Style Tags	DefiLlama		Adds readable tags to wallets so traders can understand the style or identity of the holder base.
					17	DEX Paid / Project Links / Aesthetics	DEX Screener		Reviews whether the token profile is paid or verified and checks project links, socials, and presentation quality.
